Sending Data to Logstash

Logstash is typically used to preprocess logs or metrics, parsing, enriching, and forwarding them to Elasticsearch. While Python can index directly into Elasticsearch, you might route data through Logstash to apply filtering rules or convert formats.

==========

Streaming Data from Kafka

For high-throughput pipelines, Apache Kafka is a popular buffer between producers and Elasticsearch. It decouples data ingestion and indexing, making the system more resilient and scalable.

Python can consume Kafka messages using Kafka-python and index them directly into Elasticsearch.

==========

If you're dealing with large volumes, consider batching messages and using the bulk API for better indexing performance.

==========

Can I delete only certain data from within indices?

Yes. Use the `delete_by_query` API to remove documents matching specific criteria:

```
es.delete_by_query(index='logs', body={
    'query': {
        'range': {
            'timestamp': {'lt': 'now-30d'}
        }
    }
})
```

==========

How to connect Elasticsearch with Django?

Here's a basic setup:

1. Install the client:

```
pip install elasticsearch
```

2. Use it in a Django view or task:

```
from elasticsearch import Elasticsearch
es = Elasticsearch()

def index_blog_post(post):
    doc = {
        'title': post.title,
        'content': post.content,
        'published_at': post.published_at.isoformat()
    }
    es.index(index='blog', id=post.id, body=doc)
```

For full integration (with signals, real-time sync, search views), consider using **django-elasticsearch-dsl**.
